

Wave Energy and Momentum / Wave Kinetics

- have discussed basic waves in uniform plasma, unmagnetized:

$$\text{EM: } \omega^2 = \omega_{pe}^2 + c^2 k^2 = \omega_{pe}^2 (1 + \frac{1}{2} k^2 \lambda_D^2)$$

$$\text{Warm Plasma: } \omega^2 = \omega_{pe}^2 (1 + \frac{1}{2} k^2 \lambda_{De}^2)$$

Chapman

$$\text{Ion Acoustic: } \omega^2 = k^2 c_s^2 / (1 + k^2 \lambda_{De}^2)$$

$$c_s^2 = T_e / m_i$$

- now seek general Poynting's theorem for plasma waves, especially electrostatic, i.e. a relation of form:

$$\partial_t W + \nabla \cdot \underline{S} + \underline{Q} = 0$$

$W \rightarrow$ wave energy density

$\underline{S} \rightarrow$ wave energy/density flux / Momentum

$\underline{Q} \rightarrow$ Dissipation

- issue: \rightarrow second order in wave amplitude
(i.e. quadratic)

\rightarrow need include medium energy as well as wave EM fields

In pure EM:

$$\partial_t \left(\frac{\underline{E}^2}{8\pi} + \frac{B^2}{8\pi} \right) + \underline{D} \cdot \left[\frac{c}{4\pi} \underline{E} \times \underline{H} \right] + \underline{E} \cdot \underline{J} = 0$$

- How construct:

- (a) \rightarrow can derive via Principle of Least Action, wave Lagrangian Density, leading to Action density equation
- (b) \rightarrow can derive by considering build-up of energy content in time, allowing for fast (carrier) and slow space-time dependence.

For (b):

$$\frac{dW}{dt} = \frac{1}{8\pi} \operatorname{re} \left(\underline{E}^* \cdot \frac{d\underline{D}}{dt} \right)$$

Consider:

$$\underline{E} = \underline{E}_0(t, \underline{x}) e^{i(\underline{k}_0 \cdot \underline{x} - \omega t)}$$

carrier

slow space-time
variation

$t \leftrightarrow$ build-up of
energy

$\underline{x} \leftrightarrow$ spread of initially
local perturbation

slow $t \rightarrow$ frequency ω

slow $\underline{x} \rightarrow$ wavevector \underline{k}

envelope

$$\underline{E} = \sum_{\underline{x}, \omega} \underline{E}_0_{\underline{x}, \omega} \exp[i(\underline{k}_0 + \underline{k}) \cdot \underline{x} - i(\omega_0 + \omega)t]$$

and: $D = E E$, but E non-local
in space-time

$$D(\underline{k}, \omega) = E(\underline{k}, \omega) E(\underline{k}, \omega)$$

if $F(\underline{k}, \omega) = -i\omega G(\underline{k}, \omega)$

$$\frac{dD}{dt} = \sum_{\underline{k}, \underline{q}} F(\omega_0 + \alpha, \underline{k}_0 + \underline{q}) e^{i(\underline{q} \cdot \underline{x} - \alpha t)} e^{-i(\omega_0 + \omega)t} \underline{E}_0 \left[e^{i(\underline{k}_0 \cdot \underline{x})} \right] *$$

then expand:

$$\alpha \ll \omega_0$$

$$|\underline{q}| \ll |\underline{k}|$$

$$\frac{dD}{dt} = \sum_{\underline{k}, \underline{q}} \left[-i\omega G(\underline{k}, \omega) + \alpha \frac{\partial}{\partial \omega} (-i\omega G) \Big|_{\underline{k}_0, \omega_0} + \underline{q} \cdot \frac{\partial}{\partial \underline{k}} (-i\omega G) \Big|_{\underline{k}_0, \omega_0} \right] e^{i(\underline{q} \cdot \underline{x} - \alpha t)} *$$

$$\underline{E}_0 \Big|_{\omega_0, \underline{k}_0} e^{i(\underline{k}_0 \cdot \underline{x} - \omega_0 t)}$$

operators act on all to right, so

re-summing series:

51

$$\frac{dP}{dt} = \left[-\omega \epsilon \underline{E}_0(t, \underline{x}) + \frac{\partial(\omega \epsilon)}{\partial \omega} \frac{\partial \underline{E}_0(t, \underline{x})}{\partial t} - \frac{\partial(\omega \epsilon)}{\partial \underline{k}} \cdot \underline{\nabla} \underline{E}_0(t, \underline{x}) \right] \exp \left[\underline{k} \cdot \underline{x} - i\omega t \right]$$

so

$$\frac{dW}{dt} = \frac{1}{8\pi} \operatorname{re} \left(\underline{E}^* \cdot \frac{d\underline{D}}{dt} \right)$$

and thus:

$$\begin{aligned} \frac{dW}{dt} = & \omega \epsilon_{\text{IM}}(\underline{k}, \omega) \frac{|\underline{E}_0|^2}{8\pi} \Big|_{\underline{k}, \omega} \\ & + \frac{\partial}{\partial t} \left[\frac{\partial(\omega \epsilon)}{\partial \omega} \frac{|\underline{E}_0|^2}{8\pi} \right] \Big|_{\underline{k}, \omega} \\ & - \underline{\nabla} \cdot \left[\frac{\partial(\omega \epsilon)}{\partial \underline{k}} \frac{|\underline{E}_0|^2}{8\pi} \right] \Big|_{\underline{k}, \omega} \end{aligned}$$

thus have:

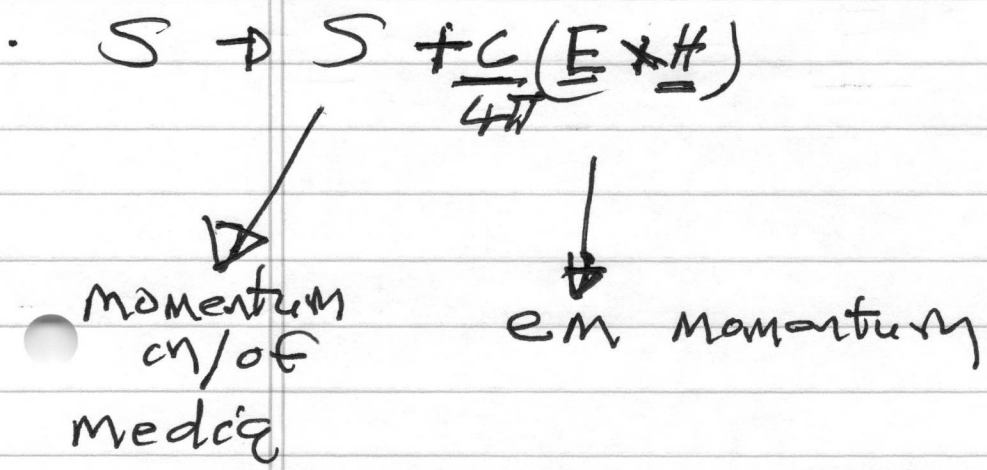

$$W = \frac{\partial}{\partial \omega} (\omega \epsilon) \Big|_{k_0, \omega_0} (|E_0|^2 / 8\pi) \rightarrow \text{total wave energy density}$$

$$S = - \frac{\partial}{\partial k} (\omega \epsilon) \Big|_{k_0, \omega_0} (|E_0|^2 / 8\pi) \rightarrow \text{total wave energy flux}$$

$$Q = \omega \epsilon_{IM} (|E_0|^2 / 8\pi) \rightarrow \text{energy dissipation rate}$$

Note: For EM wave:

$$\rightarrow W \rightarrow \frac{\partial}{\partial \omega} (\omega \epsilon) \Big|_{k, \omega} (|E_0|^2 / 8\pi) + \frac{\partial}{\partial \omega} (\omega \mu) \Big|_{k, \omega} (|H_0|^2 / 8\pi)$$

Note:

(i) At wave resonance, $\epsilon(k_0, \omega_0) = 0$

$$W = \omega \frac{\partial \epsilon}{\partial \omega} \Big|_{k_0, \omega_0} \left(|E_0|^2 / 8\pi \right)$$

$$\underline{S} = -\omega_H \frac{\partial \epsilon}{\partial k} \Big|_{k_0, \omega_0} \left(|E_0|^2 / 8\pi \right) = - \frac{\partial \epsilon / \partial k}{\partial \epsilon / \partial \omega} \Big|_{\omega_H} \omega_H \frac{\partial \epsilon}{\partial \omega} \Big|_{k_0} \left(|E_0|^2 / 8\pi \right)$$

$$Q = \omega_H \frac{\partial \epsilon}{\partial \omega} \Big|_{k_0, \omega_H} \left(|E_0|^2 / 8\pi \right) = + v_{gr} W$$

(ii) $v_{gr} = \underline{S} / W$

$$= - \left(\frac{\partial \epsilon}{\partial k} \right)_{\omega_H} / \frac{\partial \epsilon}{\partial \omega} \Big|_{\omega_H}$$

Alternatively, along wave path:

$$d\epsilon = \frac{\partial \epsilon}{\partial \omega} d\omega + \frac{\partial \epsilon}{\partial k} dk = 0$$

$$v_{gr} = - \frac{\partial \epsilon / \partial k}{\partial \epsilon / \partial \omega} \Big|_{\omega_H}$$

Physics of Wave Energy/Momentum

$$c) W = \frac{d}{d\omega} (\omega \epsilon) \left(\frac{|E_0|^2}{8\pi} \right)$$

$$\epsilon = 1 - \frac{\omega_p^2}{\omega^2}, \text{ for cold plasma}$$

$$W = \left(1 + \frac{\omega_p^2}{\omega^2} \right) \frac{|E_0|^2}{8\pi} = \frac{3}{2} \times \frac{|E_0|^2}{8\pi}$$

$\omega = \omega_p$

$$= W_{\text{Field}} + W_{\text{shaking Energy}}$$

(Wave) = Field
+ Particle Motion

Shaking?

$$\frac{1}{2} n_0 m \langle \dot{V} \rangle^2 = \frac{n_0}{2} \frac{e^2}{m} \frac{|E_0|^2}{\omega^2} = \frac{1}{8\pi} \frac{\omega_p^2}{\omega^2} |E_0|^2$$

$$d) S = -\omega \left(\frac{d\epsilon}{d\omega} \right) \frac{|E_0|^2}{8\pi}$$

$$\epsilon = 1 - \frac{\omega_p^2}{\omega^2 - k^2 v_b^2} \quad (\text{Beam Plasma})$$

v_b
beam speed

$$S = + \omega \frac{\omega_p^2}{\omega^2} \frac{2k v_b^2}{(\omega^2 - k^2 v_b^2)^2} \Rightarrow \frac{S \sim k}{\text{compression of wave}}$$

(ii) IF cold, collisional plasma

$$\epsilon = 1 - \frac{\omega_p^2}{\omega(\omega + i\nu)}$$

→ collisional drag i.e. neutrals

$$\approx 1 - \frac{\omega_p^2 (\omega - i\nu)}{\omega(\omega^2 + \nu^2)}$$

$$\frac{dV}{dt} + \nu V = \frac{e}{m} E$$

etc.

$$\epsilon_{IM} = \frac{\omega_p^2 \nu}{\omega(\omega^2 + \nu^2)}$$

$$Q = \frac{\omega_p^2 \nu}{\omega^2 + \nu^2} \frac{|E|^2}{8\pi}$$

$Q \sim \nu$

Insert

a) Positive / Negative Energy Waves

$$W = \frac{|E|^2}{8\pi} \omega \frac{\partial \epsilon / \partial \omega}{\omega_h}$$

$$= \frac{|E_h|^2}{8\pi} \frac{\partial(\omega \epsilon)}{\partial \omega}$$

Contract

→ cold plasma $\epsilon = 1 - \frac{\omega_p^2}{\omega^2}$

$$W_h = \frac{|E_h|^2}{8\pi} \left(1 + \frac{\omega_p^2}{\omega_h^2} \right)$$

$$= \frac{|E_h|^2}{4\pi}$$

Insert:

- Observer: ?

$$E_{\text{wave}} = \omega_{\text{H}} \sqrt{\frac{\partial G}{\partial \omega} \left| \frac{\partial E_0}{\partial t} \right|^2}$$

Now, semi-classically:

$$E_{\text{w}} = N \omega_{\text{H}} \hbar \rightarrow \hbar$$

$$P_{\text{w}} = N \hbar \rightarrow \hbar$$

where $N \equiv \# \text{ waves}, \# \text{ quanta}$

Dimensionally:

$$\Sigma = N \omega \Rightarrow N \sim \Sigma / \omega$$

\Rightarrow Action density

- For Action density, see Posted Notes from Mechanics.

- Action density $N(\underline{x}, \underline{k}, t)$ satisfies wave kinetic equation:

$$\partial_t N + \underline{v}_{gr} \cdot \underline{\nabla} N - \underline{\partial}_x \omega \cdot \underline{\nabla}_k N = C(N)$$

ie $\frac{dN}{dt} = C(N)$

along $\frac{d\underline{x}}{dt} = \underline{v}_{gr}$, $\frac{d\underline{k}}{dt} = -\underline{\partial}_x \omega$

IF seek $N(\underline{x}, t)$:

$$\partial_t N + \underline{\nabla} \cdot (\underline{v}_{gr} N) = \int d\underline{k} C(N)$$

for # conserving

Understood $N(\underline{x}, t)$ implies packet.

10 ~~10~~

- $\omega_H > 0 \Rightarrow$ need put energy into oscillator to excite motion

- kinetic energy $\rightarrow \frac{1}{2} m v^2$
Potential $\rightarrow |E|^2 / 8\pi$ (electrostatic)

equal in simple oscillator.

\rightarrow Beam-Plasma System $\left\{ \begin{array}{l} \underline{V} = v_0 \underline{z} + \tilde{V} \\ \text{ID} \end{array} \right.$

$$\frac{\partial \tilde{V}}{\partial t} + v_0 \frac{\partial \tilde{V}}{\partial x} = + \frac{q}{m} E$$

$$\frac{\partial \tilde{n}}{\partial t} + v_0 \frac{\partial \tilde{n}}{\partial x} = -n_0 \underline{\nabla} \cdot \underline{\tilde{V}}$$

$$\epsilon = 1 - \omega_p^2 / (\omega - kv_0)^2$$

$$\omega = kv_0 \pm \omega_p$$

$$\begin{aligned} W_H &= \omega_H \frac{\partial \epsilon}{\partial \omega} \Big|_{\omega_k} \left(|E_k|^2 / 8\pi \right) \\ &= (kv_0 \pm \omega_p) \frac{2\omega_p^2}{(\omega - kv_0)^3} \left(|E_k|^2 / 8\pi \right) \end{aligned}$$

$$= (kv_0 \pm \omega_p) \frac{2\omega_p^2}{(\pm \omega_p)^3} \left(|E_k|^2 / 8\pi \right)$$

$$W_{\pm} = (kV_0 \pm \omega_p) \frac{|E_0|^2}{4\pi} \pm \omega_p$$

Note:

$$- W_{\pm} = k \frac{(V_0 \pm \omega_p/k) |E_0|^2}{\pm \omega_p} / 4\pi$$

- (i) + root \rightarrow "fast" wave, $\omega = \omega_p + kV_0$

$$W = \left(\frac{kV_0 + \omega_p}{\omega_p} \right) () > 0$$

~ positive energy wave

(ii) - root \rightarrow "slow" wave, $\omega = -\omega_p + kV_0$

$$W = \left(\frac{kV_0 - \omega_p}{-\omega_p} \right) () = \frac{\omega_p - kV_0}{\omega_p} ()$$

$$= \left[(\omega_p - kV_0) / \omega_p \right] ()$$

$\Rightarrow W > 0$ for $kV_0 < \omega_p$

$W < 0$ for $\omega_p < kV_0$!

⊕ Negative energy wave!

What is a negative energy wave?

\rightarrow excited by extraction of energy from system

Contrast: Positive energy wave excited by input of energy into system.

\rightarrow excitation for beam \Rightarrow bunching.

\rightarrow To excite by extraction energy wave occurs in negative (active) medium

active medium \rightarrow motion \rightarrow beam
 \downarrow
 free energy.

→ Active medium suggests free energy available for relaxation
 ⇒ instability!

How to avoid?
 ↳ A dissipation!
 (dissipn → extr. energy → wave growth)
 ↳ couple to positive energy wave!
 (extr. energy ⊖, to ⊕, etc.)

N.B. Negative energy wave excited by extraction of energy from active medium

c) For destabilization by dissipation.

$$\partial_t W_n + \nabla \cdot \underline{S}_n + \mathcal{P}_n = 0$$

if $\nabla \cdot \underline{S}_n \approx 0$ (though radiative damping can destabilize negative energy wave)

⇒

$$2\gamma_n = -\mathcal{P}_n / W_n$$

Now if $W_H < 0 \rightarrow$ negative energy

$Q_H > 0 \rightarrow$ positive dissipation

$\Rightarrow \gamma_H > 0.$

Ex: Weak collisions/dissipn in beam.

(ii) For \pm -energy wave coupling:
 \Rightarrow beam-plasma system.

Idea is to couple positive energy wave
 in ~~plasma~~ with negative energy wave
 in beam.

Ex: consider beam-plasma system:

$$\epsilon = 1 - \frac{\omega_p^2}{\omega^2} - \frac{\omega_{pb}^2}{(\omega - kv_b)^2} \quad ; \quad n_b < n_0$$

$n_b = 0 \rightarrow$ (+) energy plasma oscillations only.

beam \Rightarrow negative energy waves for
 $kv_b > \omega_{pb}$

Active medium \Rightarrow beam kinetic energy.

Now, for modes:

$$\epsilon = 1 - \frac{\omega_p^2}{\omega^2} - \frac{\omega_{pb}^2}{(\omega - kv_0)^2} = 0$$

$n_b \ll n_0$, need $\omega \sim kv_0$ for third term to be relevant

$$1 - \frac{\omega_p^2}{(kv_0)^2} - \frac{\omega_{pb}^2}{\delta^2} = 0$$

$$\delta^2 = \frac{\omega_{pb}^2}{1 - \frac{\omega_p^2}{(kv_0)^2}}$$

$$= \frac{\omega_{pb}^2}{\epsilon(k, kv_0)}$$

Now; $\delta^2 > 0 \rightarrow$ frequency shift

$\delta^2 < 0 \rightarrow \omega = kv_0 \pm i|\delta| \rightarrow$ growth.

$$\delta^2 < 0 \Rightarrow (kv_0)^2 < \omega_p^2$$

$$\text{so } \epsilon(k, kv_0) < 0$$

\Rightarrow Bunching instability \rightarrow screening
 acts to enhance charge perturbation.

$$\text{Need: } \epsilon < 0 \Rightarrow kv_0 < \omega_p$$

but $n_b \ll n \Rightarrow$ easy for $\omega_b < kv_0 < \omega_p$.

Can make more explicit connection to \oplus, \ominus energy,
